

# Phantom: Privacy-Preserving Deep Neural Network Model Obfuscation in Heterogeneous TEE and GPU System

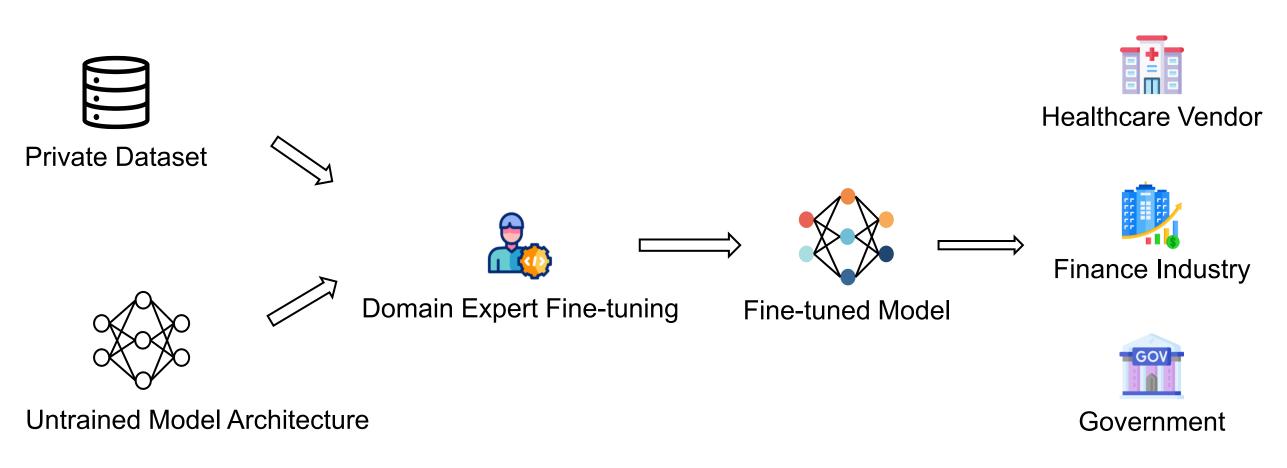

<sup>1</sup>Johns Hopkins University <sup>2</sup>Arizona State University <sup>3</sup>University of Central Florida <sup>4</sup>Sony Al

## Motivation

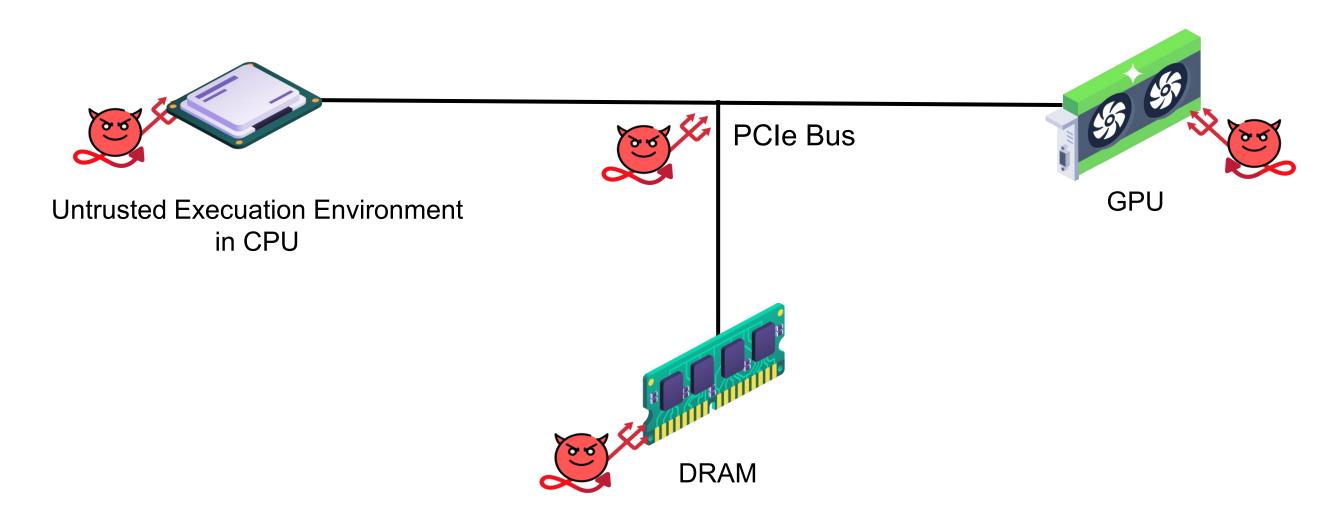

- Training costs for large-scale ML models double every 9 months
- High-stakes fields (healthcare, finance, government) require **fine-tuning ML models on private data** for domain-specific tasks.

#### Security threats

- Adversaries can exploit untrusted system components to extract model information
- DeepSteal (S&P 22')
- Hermes Attack (Security 21')
- Cache Telepathy (Security 20')
- DeepSniffer (ASPLOS 20')

# **Threat Model**

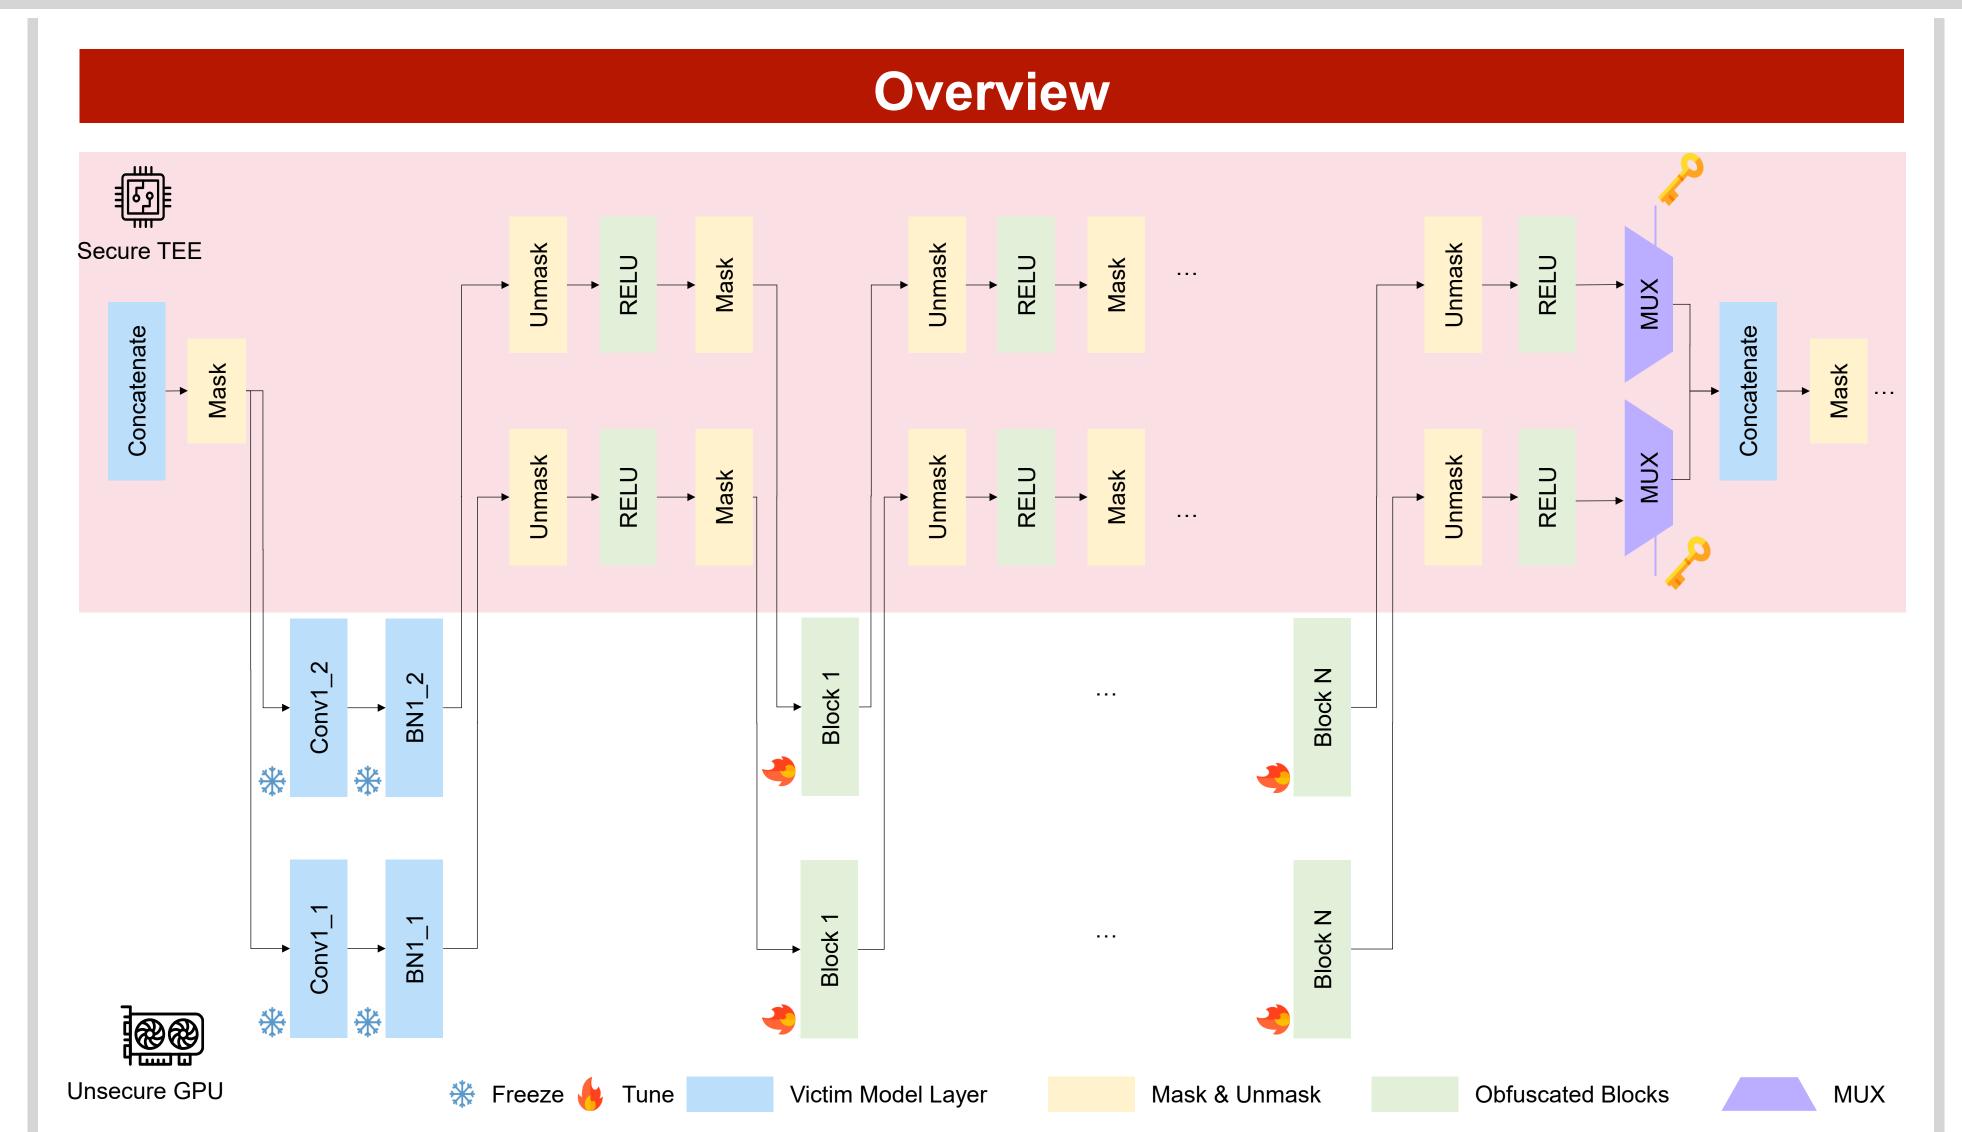

# Threat Model

- Powerful adversaries can access the untrusted execution environment (OS, GPU).
- Deployed DNN models return only class labels, not confidence scores, to both authorized users and adversaries.

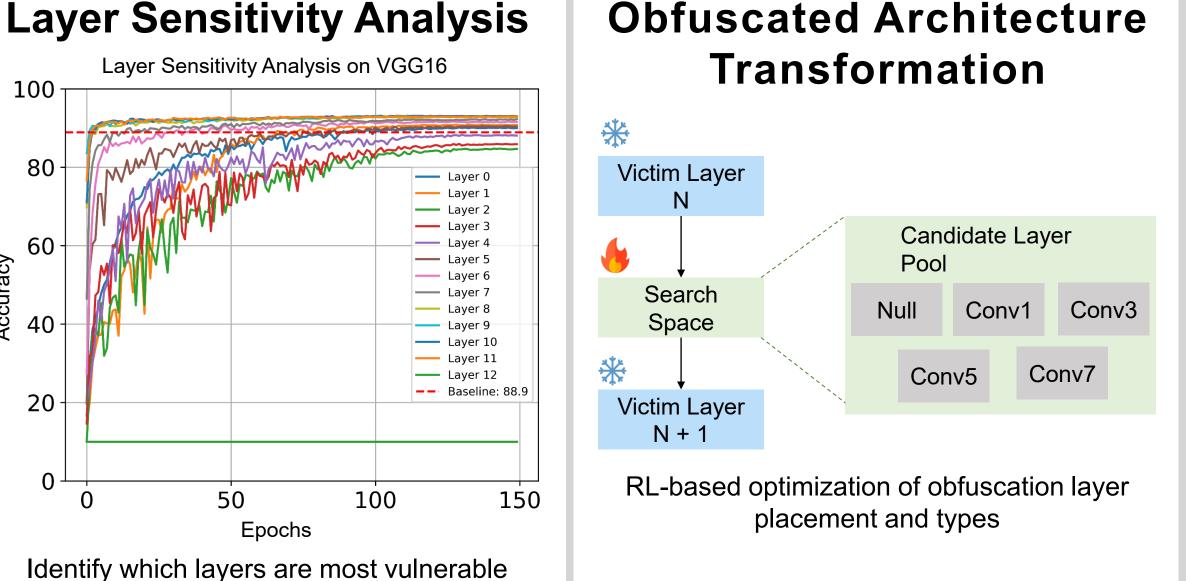

# Attack Methods

- Model Stealing Attack
- An adversary queries a victim model with limited inputs to collect input-output pairs, creating a transfer dataset.
- This dataset trains a surrogate model that replicates the victim model's behavior.
- Fine-tuning Attack
  - The adversary accesses at most 10% of the original training data and uses this limited dataset to fine-tune a partially known model (e.g., with stolen weights or architecture), recovering functionality or improving performance.

We introduces a reinforcement learning-based neural architecture search method that **injects small**, **lightweight obfuscation layers with corresponding "keys"** that determine the correct execution path.

# Methods

to attacks

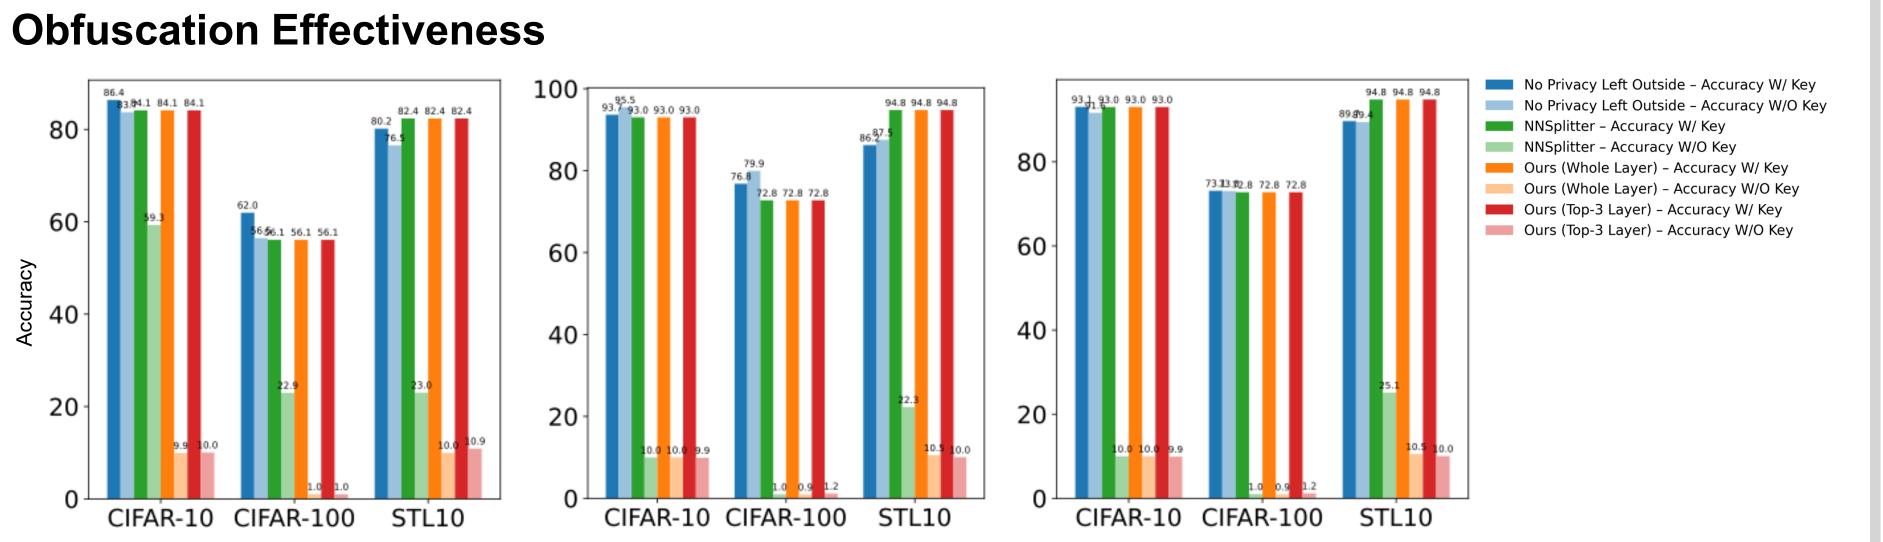

# ure Obfuscated Layer Training

- Freeze original model weights
- Train obfuscation layers to maximize loss

$$\max \mathcal{L}(\theta) = -\sum_{i=1}^{N} y_i \log(\widehat{y}_i) + (1 - y_i) \log(1 - \widehat{y}_i)$$

 Generate misleading outputs for adversaries

# Experiments

• Phantom reduces unauthorized model accuracy to near-random performance levels (e.g., ~10% on CIFAR-10/STL-10, ~1% on CIFAR-100) while maintaining full accuracy for authorized users.

## **Fine-Tuning Attack**

 Phantom demonstrates consistent defense success across all tested learning rates

- Phantom's Top-3 obfuscation strategy achieves optimal runtime performance among evaluated defenses.
- SGX 2.0 shifts the bottleneck from TEE computation to TEE-GPU data transfer, comprising 50-60% of execution time.
